OE-Mail Recovery is a simple-to-use program designed to recover broken Outlook folders and to extract emails (DBX format). It addresses all users, whether they have experience with software programs or not. The interface of the application is based on a standard window with a well-organized layout. First-time users can use the recovery wizard to effortlessly carry on a task. Once you specify a path to the folder containing the DBX files, you can view a list of all available items ready for extraction, after which you can establish a location for the extracted items; this job is done in no time, and it is possible to retrieve multiple items simultaneously. From the Options area you can make the app retrieve deleted emails as well. In addition, you can browse the hard drive for files with the DBX format by using a folder structure which resembles with the one of Windows Explorer. On the downside, you cannot minimize OE-Mail Recovery to the system tray area, make it run at system startup automatically or schedule a recovery task. The app runs on a very low quantity of CPU and system memory, so it does not affect the computer's overall performance. It has a good response time and performs a retrieval job rapidly, without causing the operating system to hang, crash or pop up error dialogs; we haven't encountered any issues throughout our testing. There is also a help file available. To sum it up, OE-Mail Recovery provides users with a simple and effective solution to extract and save emails from DBX files in Outlook.1. Field of the Invention The present invention relates to an image processing method for a color electronic camera in which information regarding image data is recorded and images are formed based on image data by control of camera control circuitry while reproducing image data for output to a printer or like apparatus. 2. Description of the Prior Art There is known a method in which image information of plural images is recorded on a recording medium as image data while a color chart is reproduced to be compared with the image data and those of the images on the color chart are checked to provide a corrected image data. The method is required to compare color chart images with actual images for correction of image data since the RGB color values of individual pixels of image data are not always the same as the RGB color values of individual pixels of a color chart. The method is also required to provide a correct image data if image data are to be reproduced in a different way from the recording conditions.
